

Angry Birds UML – Before Implementation

Angry Birds UML – After Implementation

- Instead of having the Circle and Rectangle as attributes of the different GameObjects, I used the `getBoundingBox` function in `SpriteComponent` when they were needed. This eliminated the duplicated data of `of` and `x, y` variables in both the shape class and `SpriteComponent`.
- Bird, Block and Pig are attributes of Game instead of Level. Level stores the starting positions and numbers of different GameObjects. Since the GameObjects are mainly dealt with in Game, I didn't deem it necessary for Level to know about and store the game objects themselves.
